

Nominal Variable	<p>Nominal variables are <i>categorical variables having two or more categories without any kind of order to them</i>.</p> <p>For example, a column called “name of cities” with values such as Delhi, Mumbai, Chennai, etc.</p> <p>We can see that there is no order between the variables – viz Delhi is in no particular way higher or lower than Mumbai (unless explicitly mentioned).</p>
Normal Distribution	<p>The normal distribution is the most important and most widely used distribution in statistics. It is sometimes called the bell curve, because it has a peculiar shape of a bell. Mostly, a binomial distribution is similar to normal distribution. The difference between the two is normal distribution is continuous.</p> <div data-bbox="411 533 1029 891"> <p style="text-align: center;">Standard Normal Distribution</p>  </div>
Normalization	<p>Normalization is the process of rescaling your data so that they have the same scale. Normalization is used when the attributes in our data have varying scales.</p> <p>For example, if you have a variable ranging from 0 to 1 and other from 0 to 1000, you can normalize the variable, such that both are in the range 0 to 1.</p>
Numpy	<p>NumPy is the fundamental package for scientific computing with Python. It contains among other things:</p> <ul style="list-style-type: none"> • a powerful N-dimensional array object • sophisticated (broadcasting) functions • tools for integrating C/C++ and Fortran code • useful linear algebra, Fourier transform, and random number capabilities <p>Besides its obvious scientific uses, NumPy can also be used as an efficient multi-dimensional container of generic data. Arbitrary data-types can be defined. This allows NumPy to seamlessly and speedily integrate with a wide variety of databases.</p>
